Results of Groundwater & Soil Gas Sampling Continue to Show Improvement in Subsurface Conditions in Newburgh Village

Laboratory analysis of groundwater and soil gas samples collected in January and April 2026 on Newburgh Village property demonstrate continued decreasing concentrations of TCE in groundwater, an indication that remedial work in the spring of 2025 is performing as designed.

The remedy, an underground, carbon and zero-valent iron-based permeable reaction barrier, filters the groundwater along the northern boundary of the Newburgh Village property.

All groundwater and soil gas concentrations downgradient of the remedy are below U.S. Environmental Protection Agency (EPA) Vapor Intrusion Screening Levels. The results from this sampling will be shared with EPA followed by development of a longer-term monitoring plan with oversight from EPA and the Michigan Department of Environment, Great Lakes, and Energy (EGLE). Please feel free to contact RACER Trust, EPA or EGLE with questions about the results and what they indicate.

TCE was used in the manufacturing process and is thought to have entered the groundwater as a result of use at the former GM Spring & Bumper plant in Livonia. RACER Trust is tasked with remediating the impacts under U.S. EPA oversight. There is no indication of public exposure to TCE in the groundwater in the community. Drinking water is supplied by the City of Livonia.
